Experiment No.1

1. Title:

Use var, let, const, and demonstrate basic features like template literals and destructuring; build a billing calculator with user input.

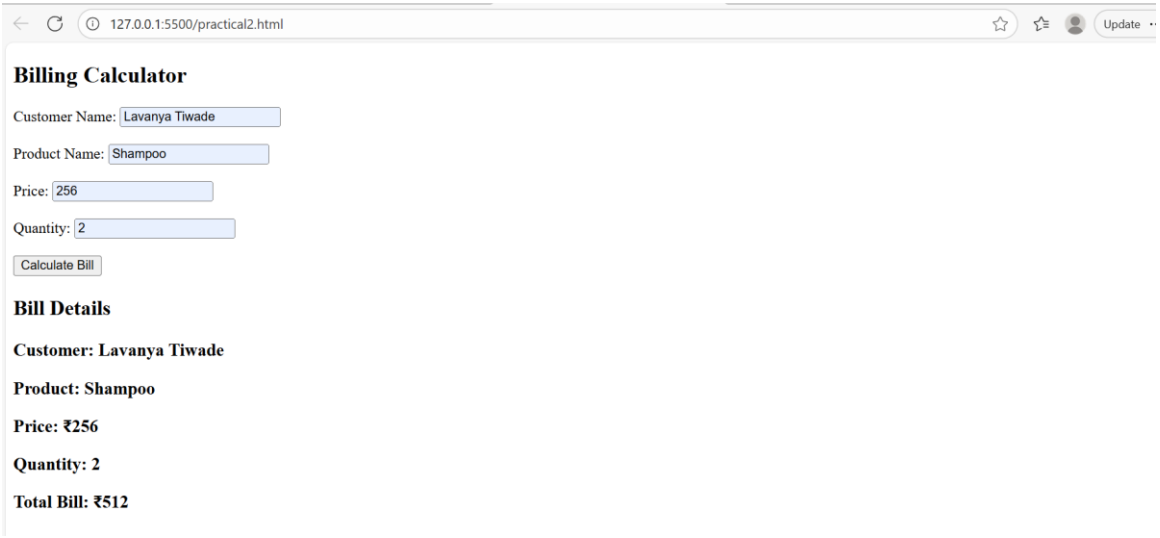

2.Software/Tools Required:

- Visual Studio Code (VS Code)
- Google Chrome / Microsoft Edge
- HTML5
- JavaScript (ES6)

3.Theory:

JavaScript provides three keywords to declare variables: **var**, **let**, and **const**. The var keyword has function scope and can be redeclared, whereas let has block scope and can be updated but not redeclared within the same scope. The const keyword is also block-scoped and is used for values that should not be reassigned. ES6 introduced **template literals**, which allow embedding variables inside strings using backticks (` `), and **destructuring**, which simplifies extracting values from arrays and objects. In this experiment, these ES6 features are demonstrated by creating a simple billing calculator that accepts user input, calculates the total bill, and displays the result.

4.Output:

5.Result/Conclusion:

This experiment helped in understanding JavaScript variable declarations (var, let, and const) and ES6 features such as **template literals** and **destructuring**. It also demonstrated how to take user input, perform calculations, and display dynamic output on a web page.
